Using Smart Cards for Remote Git Instances

Summary

This is a coauthored article by [Ryukodev](#) and myself.

While this feature is undocumented, it is possible to use a smart card to authenticate to a Git repository behind Mutual Transport Layer Security (mTLS). This product describes how to do this given a Gitea instance, a Yubikey PIV smart card and a GNU+Linux information system. The solution is to simply add the following to a user's `~/.gitconfig` file:

```
[http "https://git.example.com"]
    sslCert =
"pkcs11:model=PKCS%2315%20emulated;manufacturer=piv_II;serial=0011223344556677;token=someUserna
me"
    sslKey =
"pkcs11:model=PKCS%2315%20emulated;manufacturer=piv_II;serial=0011223344556677;token=someUserna
me"
    sslbackend = openssl
    sslkeytype = ENG
    sslcerttype = ENG
    sslCertPasswordProtected = true
```

Additionally, an authentication token must be generated for the user within Gitea (or equivalent). This is how a git pull looks like with this configuration:

```
$ git pull origin master
Password for
'cert:///pkcs11:model=PKCS%2315%20emulated;manufacturer=piv_II;serial=0011223344556677;token=someU
sername':
Username for 'https://git.example.com': someUsername
Password for 'https://someUsername@git.example.com':
From https://git.example.com/someUsername/someRepository
```

```
* branch      master  -> FETCH_HEAD
```

Already up to date.

Details

Background

Mutual TLS

In TLS, the client authenticates the server by verifying that the certificate has been cryptographically signed by a trusted certificate authority. Most commonly, this is seen when a user browses to a website. A lock icon appears next to their address bar if the server holds a proper certificate and associated private key; otherwise, an error occurs, and with the advent of HSTS, a user may be unable to browse to the website at all.

In mTLS, the server also requests the client to provide a client certificate, proving that it is signed by a certificate authority the server trusts. This is done at the protocol level, disavowing unauthorized users to even see the web app. It bears repeating: even if the server is running vCenter Server 7.0, vulnerable to CVE-2021-21985, an unauthenticated remote code execution (RCE) exploit, the attacker cannot exploit the server unless they have a private key and underlying certificate authorizing them to access vCenter.

Smart Cards

It is possible to simply hold a private key and certificate in an operating system's certificate store, allowing a signed-in user to use the certificate via a simple prompt. It's also possible to require the user to enter the encryption passphrase for the key, though in most environments, the user has the ability to turn this requirement off. Overall, one major issue remains: a password requirement for a private key used for mTLS is a form of single-factor authentication.

Enter NIST's FIPS 201-3, *Personal Identify Verification (PIV) of Federal Employees and Contractors*. Initially published in 2005, the standard defines a two-factor smart card, allowing an information system to request the user to enter an (up to) eight digit PIN before allowing the use of the private key and certificate. This effectively makes PIV devices two-factor authentication security tokens. Yubikeys officially support PIV, and this will be the primary focus of this product.

System Configuration

Prerequisites

Ensure that the `gnutls` and `openssl-pkcs11` packages are installed on your system. The former is used for `p11tool`, and the latter is used for `cURL` (the HTTP backend for `git`). For RHEL-based distros, use the following command to install:

```
sudo dnf install gnutls openssl-pkcs11 -y
```

Creating `.gitconfig`

The `.gitconfig` requires the PKCS11 URI of the certificate and key. To get the URI, use `p11tool`, like so:

```
$ p11tool --list-all-certs
warning: no token URL was provided for this operation; the available tokens are:

pkcs11:model=p11-kit-trust;manufacturer=PKCS%2311%20Kit;serial=1;token=System%20Trust
pkcs11:model=p11-kit-trust;manufacturer=PKCS%2311%20Kit;serial=1;token=Default%20Trust
pkcs11:model=PKCS%2315%20emulated;manufacturer=piv_II;serial=0011223344556677;token=someUsernam
e
```

In this case, the bottom-most line is our PIV device. This can be easily identified by the token value, which for Yubikeys is the subject name.

Create a new file, `.gitconfig`, in your home directory, containing the following data:

```
[http "https://git.example.com"]
    sslCert =
"pkcs11:model=PKCS%2315%20emulated;manufacturer=piv_II;serial=0011223344556677;token=someUserna
me"
    sslKey =
"pkcs11:model=PKCS%2315%20emulated;manufacturer=piv_II;serial=0011223344556677;token=someUserna
me"
    sslbackend = openssl
    sslkeytype = ENG
    sslcerttype = ENG
    sslCertPasswordProtected = true
```

The first line contains the URL for your Gitea (or equivalent) instance. Replace the values for `sslCert` and `sslKey` with your URI collected via the `p11tool` command above.

Gitea Configuration

These steps are specific to Gitea, but similar features are available for popular Git-based source code repository services like Bitbucket, GitLab, or GitHub Enterprise.

First, login and then press on your profile picture in the top right:

Select "Settings":

Then, select "Applications":

You will be brought to the following screen. Here, you can define a token with granular permissions. This token will be used after the mTLS authentication to the web server. The menu initially looks like so:

A dark-themed form for creating an access token. At the top is the title 'Access tokens'. Below it is a descriptive sentence: 'These tokens grant access to your account using the Forgejo API.' The main section is titled 'Generate new token'. It contains a 'Token name' label followed by a text input field with a vertical cursor. Below the input field is the section 'Repository and Organization Access', which includes two radio button options: 'Public only' and 'All (public, private, and limited)'. The second option is selected, indicated by an orange dot. Below the radio buttons is a link '► Select permissions'. At the bottom of the form is an orange button labeled 'Generate token'.

In our case, we set the token to have access to all public, private and limited repositories and organizations; and we allow read and write access to repositories:

Access tokens

These tokens grant access to your account using the Forgejo API.

Generate new token

Token name

Git

Repository and Organization Access

☐ Public only

☒ All (public, private, and limited)

▼ Select permissions

Selected token permissions limit authorization only to the corresponding API

activitypub

No access

admin

No access

issue

No access

misc

No access

notification

No access

organization

No access

package

No access

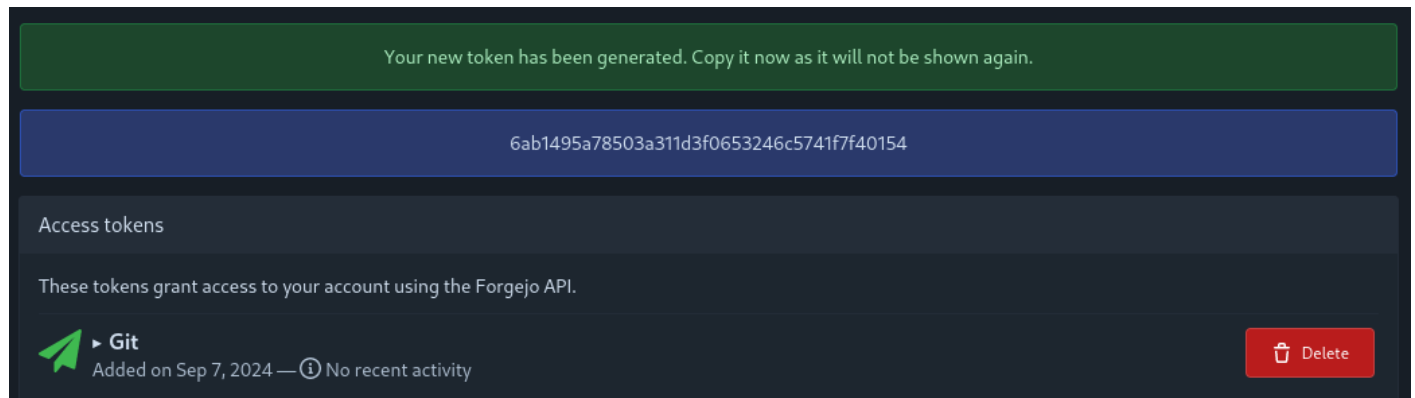

repository

Read and write

user

No access

Then, press "Generate token". You will be brought to the following screen, where the token secret is display:

You must save this secret and use it every time you wish to do a Git operation on the remote instance

This is how a git pull looks like with this configuration:

```
$ git pull origin master
Password for
'cert:///pkcs11:model=PKCS%2315%20emulated;manufacturer=piv_II;serial=0011223344556677;token=someU
sername':
Username for 'https://git.example.com': someUsername
Password for 'https://someUsername@git.example.com':
From https://git.example.com/someUsername/someRepository
* branch      master    -> FETCH_HEAD
Already up to date.
```

Git will first prompt you for your PIV PIN. Then, it will prompt for the username and the token password.

OpenZFS Issue #15526

Patch and Mitigation for Older Versions

SUBSTANTIAL REVISION: Issue #15526 has been patched in ZFS versions 2.2.2 and 2.1.14, according to open source reporting. The mitigation below only applies to older versions of ZFS.

Summary

A silent data corruption bug exists in ZFS versions 2.1.4 up to 2.1.13, 2.2.0 and 2.2.1, per [this GitHub issue](#). Versions 2.2.2 and 2.1.14 have patched the issue, according to [open source reporting](#).

A ZFS scrub will not identify any data corrupted by this bug. The only high-assurance method to check if any files were corrupted is to compare files within ZFS to their copies stored outside of ZFS.

If you are still using an older version of ZFS that is impacted by this issue, you may significantly lower the chance that this issue impacts your file system by setting the ZFS parameter `zfs_dmu_offset_next_sync` to 0. Note that this does not prevent the issue from occurring, per [this GitHub comment](#), but it does lower the chance that silent data corruption occurs.

Details

Mitigation

Linux

Runtime

To apply the mitigation in runtime, run the following command as the root user:

```
echo 0 > /sys/module/zfs/parameters/zfs_dmu_offset_next_sync
```

Permanent

To apply the mitigation permanently, create a file in `/etc/modprobe.d/` such as:

```
/etc/modprobe.d/mitigation.conf
```

Containing the following:

```
options zfs zfs_dmu_offset_next_sync=0
```

FreeBSD

Runtime

To apply the mitigation in runtime, run the following command as the root user:

```
sysctl -w vfs.zfs.dmu_offset_next_sync=0
```

Permanent

To apply the mitigation permanently, append the following line to `/etc/sysctl.conf`:

```
vfs.zfs.dmu_offset_next_sync=0
```

Reproducing the Bug

Linux

To reproduce the bug in Linux, use the script below (copy pasted from the following [gist](#)):

```
#!/bin/bash
#
# Run this script multiple times in parallel inside your pool's mount
```

```
# to reproduce https://github.com/openzfs/zfs/issues/15526. Like:
#
# ./reproducer.sh & ./reproducer.sh & ./reproducer.sh & ./reproducer.sh & wait
#

# if [ $(cat /sys/module/zfs/parameters/zfs_bclone_enabled) != "1" ] ; then
#   echo "please set /sys/module/zfs/parameters/zfs_bclone_enabled = 1"
#   exit
# fi

prefix="reproducer_${BASHPID}_"
dd if=/dev/urandom of=${prefix}0 bs=1M count=1 status=none

echo "writing files"
end=1000
h=0
for i in `seq 1 2 $end` ; do
  let "j=i+1"
  cp ${prefix}$h ${prefix}$i
  cp --reflink=never ${prefix}$i ${prefix}$j
  let "h++"
done

echo "checking files"
for i in `seq 1 $end` ; do
  diff ${prefix}0 ${prefix}$i
done
```

FreeBSD

To reproduce the bug in FreeBSD, use the script below (copy pasted from the following [post](#)):

```
#!/bin/bash
#
# Run this script multiple times in parallel inside your pool's mount
# to reproduce https://github.com/openzfs/zfs/issues/15526. Like:
#
# ./reproducer.sh & ./reproducer.sh & ./reproducer.sh & ./reproducer.sh & wait
#
```

```

# if [ $(cat /sys/module/zfs/parameters/zfs_bclone_enabled) != "1" ] ; then
#     echo "please set /sys/module/zfs/parameters/zfs_bclone_enabled = 1"
#     exit
# fi

prefix="reproducer_${BASHPID}_"
dd if=/dev/urandom of=${prefix}0 bs=1M count=1 status=none

echo "writing files"
end=1000
h=0
for i in `seq 1 2 $end` ; do
    let "j=i+1"
    cp ${prefix}$h ${prefix}$i
    cp ${prefix}$i ${prefix}$j
    let "h++"
done

echo "checking files"
for i in `seq 1 $end` ; do
    diff ${prefix}0 ${prefix}$i
done

```

Commentary

I was unable to reproduce this issue in TrueNAS Core 13.0-U5.3 (FreeBSD) but I was able to reproduce it in Proxmox 8.0.4 (Debian).

```

Butane - Explanation

On line 7, add your SSH public key to be able to sign into your Fedora CoreOS machine. We add the Docker repository as a file. Then, we use some systemd trickery to remove docker, runc and containerd. These are installed by default in Fedora CoreOS, but conflict with the up-to-date versions of Docker, so we remove them. The next service waits for the uninstall service to complete, and installs docker per the Fedora installation guide [here](#).

Your Fedora CoreOS system will reboot in 10 minutes after running these systemd services. It's unfortunately impossible to apply software removals live, so a restart is required. If you wish to restart sooner, you can run `systemctl reboot` manually.

Why?

Podman doesn't have the equivalent of Docker Compose. Per the [suggestion](#) of the Podman development team, we can simply use Docker Compose with a Podman backend. There needs to be some trickery done to support building images with a Podman backend, which can be seen [here](#).

Overall, I found Podman to be more trouble than it's worth. As I worked with Podman for nearly a year, I ran into constant incompatibilities and oddities that had me searching for workarounds for things that should *just work*. Simply running the latest version of Docker and Docker Compose not only meets my needs, but is stable—I have yet to have any breaking changes due to automatic updates with Docker and Docker Compose v2.

Importing VMs from TrueNAS Core (Bhyve) to Proxmox

Summary

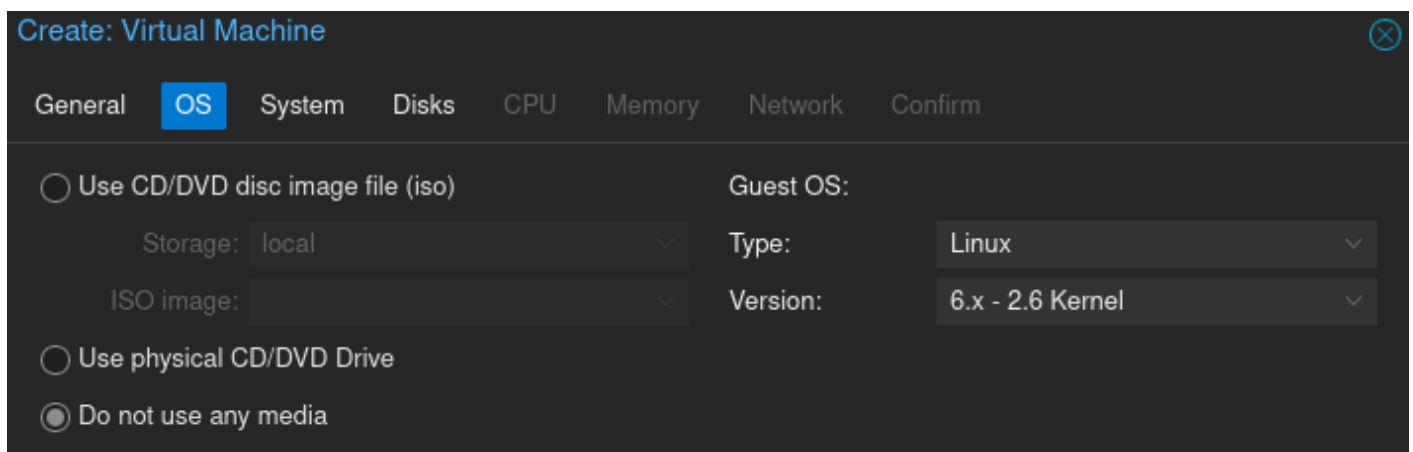

This page explains the process of importing VMs from TrueNAS Core, which uses FreeBSD's [Bhyve](#) for virtualization, to Proxmox.

Details

Proxmox

In Proxmox, create a new VM and note its VM number. When creating the VM, follow these guidelines:

In the OS section, select "Do not use any media"

The screenshot shows the 'Create: Virtual Machine' window in Proxmox, with the 'OS' tab selected. The window has a dark theme and a close button in the top right corner. The 'General' tab is also visible. The 'OS' section contains three radio buttons: 'Use CD/DVD disc image file (iso)', 'Use physical CD/DVD Drive', and 'Do not use any media'. The 'Do not use any media' option is selected. To the right of the radio buttons, there are two dropdown menus: 'Guest OS:' with 'Linux' selected, and 'Version:' with '6.x - 2.6 Kernel' selected. Below the radio buttons, there are two more dropdown menus: 'Storage:' with 'local' selected, and 'ISO image:' with a dropdown arrow.

In the System section, select "OVMF (UEFI)" for BIOS. Also select EFI Storage to be the same dataset as where you would like your VM's disk to be. We chose the default local-zfs dataset, but you may choose any other dataset, such as an encrypted dataset if you want your VMs to be encrypted.

Create: Virtual Machine ✕

GeneralOSSystemDisksCPUMemoryNetworkConfirm

Graphic card:Default

Machine:Default (i440fx)

Firmware

BIOS:OVMF (UEFI)

Add EFI Disk:☒

EFI Storage:local-zfs

Format:Raw disk image (raw)

Pre-Enroll keys:☒

SCSI Controller:VirtIO SCSI single

Qemu Agent:☐

Add TPM:☐

In the disk section, remove the default disk and do not set a disk.

Create: Virtual Machine

GeneralOSSystemDisksCPU

No Disks

Continue with the rest of the sections per your own personal requirements.

TrueNAS

Shutdown the VM in TrueNAS and make a snapshot of the VM dataset in TrueNAS. Login to SSH in TrueNAS as the root user and run the following command to send the dataset using SSH to Proxmox:

```
zfs send [VM_Dataset]@[snapshot_name] | ssh root@proxmox 'zfs receive rpool/[any dataset here]/vm-[num]-disk-1'
```

If you use DHCP in your network and you would like your IP address for the VM to be identical after migration, press the devices button in your virtual machine menu:

Virtual Machines

COLUMNS

ADD

Name	State	Autostart
<div> <div>Virtual CPUs: 1</div> <div>Cores: 2</div> <div>Threads: 1</div> <div>Memory Size: 8.00 GiB</div> <div>Boot Loader Type: UEFI</div> <div>System Clock: LOCAL</div> <div>VNC Port: 31449</div> <div>Com Port: /dev/nmdm2B</div> <div>Description:</div> <div>Shutdown Timeout: 90 seconds</div> </div> <div> <div>▶ START</div> <div> EDIT</div> <div> DELETE</div> <div> DEVICES</div> <div> CLONE</div> </div>		

Then, press the three dots over the "NIC" device and press Edit.

Device ID	Device	Order
14	NIC	1002
15	DISK	1001
16	VNC	1002

1 - 3 of 3

⋮

Edit

Delete

Change Device Order

Details

A new menu should show up which displays the MAC address. Copy this MAC address. In Proxmox, you may edit your Network Device and paste the MAC address there.

Back to Proxmox

Back in Proxmox, login to the root shell and run the `qm rescan` command. Then, go into your VM's hardware menu. The disk should show up as an unattached device. You may now attach it.

Congratulations, you have successfully migrated a virtual machine from TrueNAS Core to Proxmox!
