

Analyzing SWTPM Logs with Wireshark

This article aims to bridge the gap for Trusted Platform Module (TPM) log analysis. SWTPM is a software Trusted Platform Module emulator developed by David Safford and Stefan Berger at IBM. SWTPM logs display hexadecimal bytes sent to and from SWTPM, but no human-readable logs are available. Per the [author](#) of SWTPM, it's possible to use the `ioctl` definitions and Trusted Computing Group (TCG) paperwork in order to decode the traffic by hand. Wireshark has a high quality TPM traffic decoder, but it doesn't work with the log files from SWTPM unless they've been converted to a PCAP file, first.

When I initially wrote this article, there was no native way to write the logs as a PCAP file. I mentioned this to Stefan Berger, and he was kind enough to [implement](#) a PCAP writer in SWTPM natively using the `--pcap` option. This option is currently available in the master branch; in the meantime, for versions of SWTPM packaged in Linux distributions, including Debian which Proxmox runs on, it's possible to convert the hexadecimal logs a PCAP using the open source [swtpm-log-to-pcap](#) script. This article walks through using the script for logs generated by a Proxmox virtual machine with the SWTPM enabled.

Attached in the top left is an SWTPM log and a PCAP generated using the `swtpm-log-to-pcap` script, if you wish to skip ahead and see the capability for yourself.

Background

Trusted Platform Modules (TPMs) are hardware root of trust devices that are used in cryptographic operations, often in conjunction with full-disk encryption and secure boot. Articles and resources for TPM traffic analysis are quite sparse, making it difficult to test TPM configurations and validate whether the TPM is behaving correctly.

SWTPM is a software implementation of TPMs. You may be familiar with `swtpm` if you ever used Proxmox's TPM feature, which wholly relies on SWTPM. SWTPM logs simply dump the hexadecimal bytes of traffic to the TPM and from the TPM, but no decoding or other details are available in the official logs. In this [GitHub discussion](#), the author of SWTPM suggests simply referring to `ioctl` definitions and TCG paperwork in order to decode the traffic by hand.

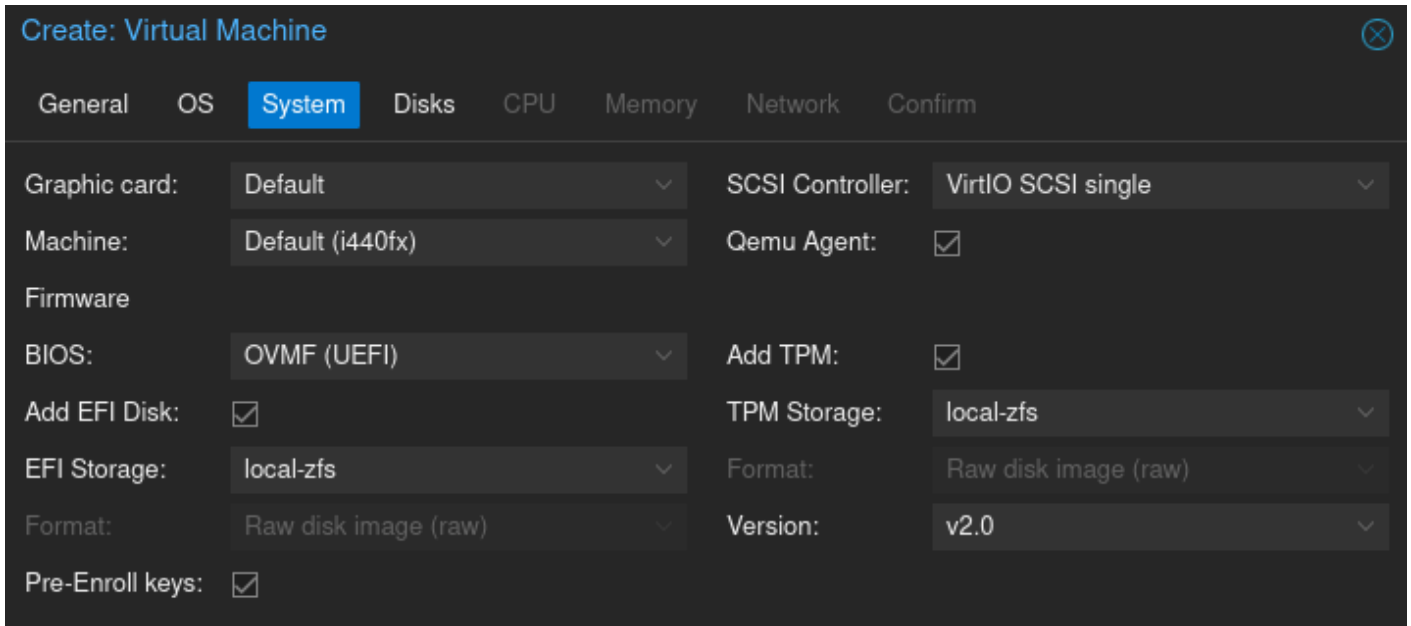

Thankfully, Wireshark has a packet dissector for the TPM protocol. All you need to do is use [swtpm-log-to-pcap](#), a small script I published on GitHub, to convert the logs to a PCAP. This script was

made possible by Philippe Biondi and community's packet manipulation tool [Scapy](#).

Proxmox Walkthrough

Setting Up a Virtual Machine with TPM Support

In Proxmox, create a virtual machine with a TPM 2.0 device. The setting is available in the System tab of the Virtual Machine creation menu:

The screenshot shows the 'Create: Virtual Machine' dialog box in Proxmox, with the 'System' tab selected. The settings are as follows:

Setting	Value
Graphic card:	Default
Machine:	Default (i440fx)
SCSI Controller:	VirtIO SCSI single
Qemu Agent:	<input checked="" type="checkbox"/>
BIOS:	OVMF (UEFI)
Add TPM:	<input checked="" type="checkbox"/>
TPM Storage:	local-zfs
Add EFI Disk:	<input checked="" type="checkbox"/>
EFI Storage:	local-zfs
Format:	Raw disk image (raw)
Version:	v2.0
Pre-Enroll keys:	<input checked="" type="checkbox"/>

Modifying Proxmox scripts to enable verbose logging

After creating a virtual machine with a TPM attached, we need to modify a Proxmox script to increase SWTPM verbosity.

Modifying Proxmox scripts is not an officially supported action, so a Proxmox update may revert these changes. If you notice that the changes were reverted after an update, simply repeat the steps below.

Login to Proxmox as the root user and open the `/usr/share/perl5/PVE/QemuServer.pm` with a text editor like `vim`:

```
vim /usr/share/perl5/PVE/QemuServer.pm
```

Then, navigate to line 2892 pictured below. Note that depending on your Proxmox version, this line may be elsewhere. All you're looking for is the line that contains the log level and log file location for SWTPM:

```
"file=/run/qemu-server/$vmid-swtpm.log,level=1,prefix=$log_prefix"
```

```
my $emulator_cmd = [  
  "swtpm",  
  "socket",  
  "--tpmstate",  
  "backend-uri=file://$state,mode=0600",  
  "--ctrl",  
  "type=unixio,path=$paths->{socket},mode=0600",  
  "--pid",  
  "file=$paths->{pid}",  
  "--terminate", # terminate on QEMU disconnect  
  "--daemon",  
  "--log",  
  "file=/run/qemu-server/$vmid-swtpm.log,level=1,prefix=$log_prefix",  
];
```

Change the verbosity from 1 to 20, so that the script looks like so:

```
"file=/run/qemu-server/$vmid-swtpm.log,level=20,prefix=$log_prefix",
```

Per the above script, the SWTPM log will be in `/run/qemu-server/$vmid-swtpm.log`.

Then, restart the following services for the change to take effect.

Running these commands will cause the web UI to become unresponsive, so doing this over SSH is recommended. If you choose to use the web shell, simply reload the page when it becomes unresponsive after each command.

```
systemctl restart pveproxy  
systemctl restart pvedaemon
```

In the older Proxmox version 8, the services are instead called `pvproxy` and `pvdaemon`, respectively.

Confirm that when launching your VM, your log verbosity is set to 20, by grepping for the virtual machine process:

```
ps aux | grep swtpm.log,level --color=always
```

You should see output similar to what's pictured below, confirming that you have log level 20:

```
root@pvel:~# ps aux | grep swtpm.log,level --color=always
root      881925  0.1  0.0 15944 5268 ?        S    23:01   0:00 swtpm socket --tpmstate backend-uri=file:///dev/zvol/rpool/data/vm-103-disk-2,mode=0600 --ctrl type=unixio,path=/var/run/qemu-server/103.swtpm,mode=0600 --pid file=/var/run/qemu-server/103.swtpm.pid --terminate --daemon --log file=/run/qemu-server/103-swtpm.log,level=20,prefix=[id=1770793277] --tpm2
```

Using SWTPM and collecting the logs

Use your VM and the TPM in your virtual machine. For this example, we'll simply install the virtual machine with LUKS full-disk encryption (FDE), and add the TPM as a disk decryption device. This operation will utilize the TPM and generate some very noisy logs to look at!

```
[admin@localhost ~]# sudo systemd-cryptenroll --tpm2-device auto /dev/sda3

We trust you have received the usual lecture from the local System
Administrator. It usually boils down to these three things:

#1) Respect the privacy of others.
#2) Think before you type.
#3) With great power comes great responsibility.

For security reasons, the password you type will not be visible.

[sudo] password for admin:
Please enter current passphrase for disk /dev/sda3: .....
New TPM2 token enrolled as key slot 1.
[admin@localhost ~]# _
```

The above command introduces a privilege escalation vulnerability wherein an adversary with physical access can drop to a root shell while bypassing full disk encryption. This is a simple example and should not be used in a production setup of TPM-based LUKS FDE automatic unlock.

Export the SWTPM logs from Proxmox via scp or a similar mechanism:

```
scp root@proxmox.home.local:/run/qemu-server/103-swtpm.log .
```

Converting the logs to a PCAP

Install `swtpm-log-to-pcap`:

```
git clone https://github.com/henryreed/swtpm-log-to-pcap.git
cd swtpm-log-to-pcap
python3 -m venv venv
source venv/bin/activate
```

```
pip install -r requirements.txt
```

Run the script against your log file:

```
./swtpm-log-to-pcap.py 103-swtpm.log 103-swtpm.pcap
```

Now, logs like these:

```
[id=1770793277] SWTPM_IO_Write: length 546

```

Will be displayed like this in Wireshark:

The screenshot displays the Wireshark network protocol analyzer interface. The main window title is '103-swtpm.pcap'. The menu bar includes File, Edit, View, Go, Capture, Analyze, Statistics, Telephony, Wireless, Tools, and Help. The toolbar contains various icons for file operations and analysis. The left pane shows a list of captured packets, with the selected packet (4214) highlighted in blue. The right pane shows the detailed view of the selected packet, which is a TPM2.0 Protocol message. The detailed view is expanded to show the Authorization Area and Session attributes. The Session attributes section shows that 'SESSION_DECRYPT' is set. The bottom status bar indicates 'SESSION_DECRYPT (tpm.auth_attrs_decrypt), 1 byte'.

Conclusion

By leveraging the open source community's tooling, it's possible to rapidly accelerate system security research efforts by developing and using small scripts like swtpm-log-to-pcap. This script allows embedded developers to verify that their tooling is correctly using SWTPM before production deployment, and information security researchers to identify vulnerabilities by inspecting and decoding the TPM traffic. Special thanks to the developers and community contributors of Proxmox, SWTPM, Scapy, and Wireshark; and thanks to Stefan Berger for implementing this feature natively in SWTPM.
